

ON ELECTRIC ANISOTROPY INDUCED IN DIAMAGNETICS  
BY A STRONG ALTERNATING MAGNETIC FIELD

S. KIELICH

Received 23 March 1967

Electric anisotropy, to an amount measurable by present experimental techniques, is shown to be induced in diamagnetics by a strong magnetic field, thus in quinoline, nitrobenzene or similar liquids. In the case of an oscillating magnetic field the effect is characterized moreover by dispersion and absorption involving a relaxation time  $\tau_2$  of the magnetically anisotropic molecules. Simple formulas are proposed and employed for computing numerically the magnetically induced electric anisotropy for several liquids.

Applying a semi-macroscopic theory of nonlinear phenomena in dielectrics [1], a diamagnetic medium can be shown to become nonlinear in the presence of a strong magnetic field  $H$ , the variations in

\* Values of  $n$  and  $K\lambda$  for  $t = 20^\circ\text{C}$  are from ref. 9, whereas those of  $\delta_m/\delta_o$  are calculated from ref. 8.

medium due to the strong magnetic field;  $\chi_e$  and  $\chi_m$  are the electric and magnetic susceptibilities, and  $p$  the pressure.

Eq. (1) yields the difference in diagonal components  $\epsilon_{\sigma\tau}$  measured along the  $x$ - and  $z$ -axis as

$$\epsilon_{zz}^H - \epsilon_{xx}^H = B_{em} (H_z^2 - H_x^2), \tag{4}$$

which defines only the electric anisotropy induced in the isotropic medium by the strong magnetic field (not depending on magnetostriction).

The constant  $B_{em}$  is in general of a mathematically complicated form, and for linearly polarizable molecules can be written in molecular statistical form as

$$B_{em} = \frac{2\pi}{15\sqrt{kT}} \left(\frac{\epsilon+2}{3}\right)^2 \left\{ \left\langle \sum_{p=1}^N \sum_{q=1}^N \left( 3a_{\alpha\beta}^e(p) a_{\alpha\beta}^m(q) - a_{\alpha\alpha}^e(p) a_{\beta\beta}^m(q) \right) \right\rangle + \frac{1}{kT} \left\langle \sum_{p=1}^N \sum_{q=1}^N \sum_{r=1}^N \left( 3m_{\alpha}^{(p)} m_{\beta}^{(q)} a_{\alpha\beta}^m(r) - m_{\alpha}^{(p)} m_{\alpha}^{(q)} a_{\beta\beta}^m(r) \right) \right\rangle \right\}, \tag{5}$$

where  $m_{\alpha}^{(p)}$  is the electric dipole moment of the  $p$ -th molecule immersed in the medium,  $a_{\alpha\beta}^e(p)$  and  $a_{\alpha\beta}^m(p)$  are tensors of its electric and magnetic linear polarizabilities, and the symbol  $\langle \rangle$  denotes classical statistical averaging in the absence of external fields.

It is highly interesting to consider the case when the isotropic medium is acted on by a strong magnetic field  $H = H_0 \cos \omega t$  oscillating at frequency  $\omega$ . Here, in calculating the quadratic change in electric permittivity, one can recur to molecular relaxational theory [4,5], obtaining for the electric anisotropy constant

$$B_{em}^{\omega} = \frac{2\pi\rho}{15kT} \left(\frac{\epsilon+2}{3}\right)^2 \left( \delta_e \delta_m + \frac{\mu^2 \delta_m}{kT} \right) \left\{ 1 + \frac{\exp(i 2\omega t)}{1 + i 2\omega\tau_2} \right\}, \tag{6}$$

with  $\delta_e = a_{33}^e - a_{11}^e$  and  $\delta_m = a_{33}^m - a_{11}^m$  denoting the electric and magnetic molecular anisotropies.

its electric properties being given by the electric permittivity tensor

$$\epsilon_{\sigma\tau}^H - \epsilon_{\sigma\tau} = F_{em} \epsilon_{\sigma\tau\nu} H_{\nu} + A_{em} \delta_{\sigma\tau} H^2 + B_{em} (H_{\sigma} H_{\tau} - \frac{1}{3} \delta_{\sigma\tau} H^2), \tag{1}$$

where  $\epsilon$  is the dielectric constant at  $H=0$ , and  $\epsilon_{\sigma\tau\nu}$  is the Levi-Civita extensor.

The first term in eq. (1) describes the linear effect, similar to the well-known Faraday effect [2]. Namely, we have from eq. (1) for the difference between the non-diagonal components

$$\epsilon_{xy} - \epsilon_{yx} = 2 F_{em} H_z, \tag{2}$$

if the external magnetic field is applied along the  $z$ -axis.

The constant  $A_{em}$  in eq. (1) describes variations in  $\epsilon_{\sigma\tau}$ , isotropic and quadratic in  $H$ , related i.a. with magnetostriction (the other effects are not considered here) [3]

$$A_{em} = 2\pi \chi_e \partial(\chi_m V) / \partial p \tag{3}$$

resulting from changes in volume  $V$  of the medium due to the strong magnetic field;  $\chi_e$  and  $\chi_m$  are the electric and magnetic susceptibilities, and  $p$  the pressure.

Eq. (1) yields the difference in diagonal components  $\epsilon_{\sigma\tau}$  measured along the  $x$ - and  $z$ -axis as

$$\epsilon_{zz}^H - \epsilon_{xx}^H = B_{em} (H_z^2 - H_x^2), \tag{4}$$

which defines only the electric anisotropy induced in the isotropic medium by the strong magnetic field (not depending on magnetostriction).

The constant  $B_{em}$  is in general of a mathematically complicated form, and for linearly polarizable molecules can be written in molecular statistical form as

$$B_{em} = \frac{2\pi}{15\sqrt{kT}} \left(\frac{\epsilon+2}{3}\right)^2 \left\{ \left\langle \sum_{p=1}^N \sum_{q=1}^N \left( 3a_{\alpha\beta}^e(p) a_{\alpha\beta}^m(q) - a_{\alpha\alpha}^e(p) a_{\beta\beta}^m(q) \right) \right\rangle + \frac{1}{kT} \left\langle \sum_{p=1}^N \sum_{q=1}^N \sum_{r=1}^N \left( 3m_{\alpha}^{(p)} m_{\beta}^{(q)} a_{\alpha\beta}^m(r) - m_{\alpha}^{(p)} m_{\alpha}^{(q)} a_{\beta\beta}^m(r) \right) \right\rangle \right\}, \tag{5}$$

where  $m_{\alpha}^{(p)}$  is the electric dipole moment of the  $p$ -th molecule immersed in the medium,  $a_{\alpha\beta}^e(p)$  and  $a_{\alpha\beta}^m(p)$  are tensors of its electric and magnetic linear polarizabilities, and the symbol  $\langle \rangle$  denotes classical statistical averaging in the absence of external fields.

It is highly interesting to consider the case when the isotropic medium is acted on by a strong magnetic field  $H = H_0 \cos \omega t$  oscillating at frequency  $\omega$ . Here, in calculating the quadratic change in electric permittivity, one can recur to molecular relaxational theory [4,5], obtaining for the electric anisotropy constant

$$B_{em}^{\omega} = \frac{2\pi\rho}{15kT} \left(\frac{\epsilon+2}{3}\right)^2 \left( \delta_e \delta_m + \frac{\mu^2 \delta_m}{kT} \right) \left\{ 1 + \frac{\exp(i 2\omega t)}{1 + i 2\omega\tau_2} \right\}, \tag{6}$$

with  $\delta_e = a_{33}^e - a_{11}^e$  and  $\delta_m = a_{33}^m - a_{11}^m$  denoting the electric and magnetic molecular anisotropies.

The above result is for a diamagnetic of density  $\rho$ , with axially-symmetric molecules presenting a permanent dipole  $\mu$  and relaxation time  $\tau_2$  related with that of Debye as  $\tau_D = 3\tau_2$ . If in particular  $\omega = 0$ , eq. (6) yields the well known result [2,6,7].

Eq. (6) shows that in the case of an oscillating magnetic field the constant  $B_{em}$  is a complex quantity and can be resolved into real and imaginary parts

$$B_{em}^{\omega} = B'_{em} - i B''_{em},$$

wherein the constants, defining dispersion and absorption, are

$$B'_{em} = \frac{1}{2} B_{em}^0 \left\{ 1 + \frac{\cos 2\omega t + 2\omega\tau_2 \sin 2\omega t}{1 + 4\omega^2\tau_2^2} \right\}, \quad B''_{em} = B_{em}^0 \frac{2\omega\tau_2 \cos 2\omega t - \sin 2\omega t}{1 + 4\omega^2\tau_2^2}, \quad (7)$$

with  $B_{em}^0$  given by eq. (6) for  $\omega = 0$ .

In the case of nondipolar substances the magnetically induced electric anisotropy constant  $B_{em}$  is related with the measured Cotton-Mouton constant  $C_{\lambda}$  as follows:

$$B_{em} = 2n\lambda \left( \frac{\epsilon + 2}{n^2 + 2} \right)^2 \frac{\delta_e}{\delta_o} C_{\lambda}, \quad (8)$$

where  $n$  is the refractive index,  $\lambda$  the light wavelength, and  $\delta_o = a_{33}^o - a_{11}^o$  the optical molecular anisotropy.

For the general case of dipolar substances we have instead of eq. (8)

$$B_{em} = 2n\lambda \left( \frac{3}{n^2 + 2} \right)^2 \frac{\delta_m}{\delta_o} K_{\lambda}, \quad (9)$$

where  $K_{\lambda}$  is the measured Kerr constant.

For benzene at  $t = 20^{\circ}\text{C}$  we have  $n = 1.503$ ,  $\epsilon = 2.28$  and [8]  $C_{\lambda} = 56.7 \times 10^{-14}$ , and eq. (8) on assuming  $\delta_e \approx \delta_o$  leads to an electric anisotropy of  $B_{em} = 0.94 \times 10^{-16}$ . On the other hand, we have [8]  $\delta_o = -3.84 \times 10^{-24}$ ,  $\delta_m = -9.7 \times 10^{-29}$  and [9]  $K_{\lambda} = 40.3 \times 10^{-9}$ , whence eq. (9) yields  $B_{em} = 0.8 \times 10^{-16}$ . Thus, eqs. (8) and (9) are found to yield values of  $B_{em}$  for benzene that are in sufficiently good agreement.

Owing to the fact that, quite recently, Le Fèvre and Murthy [8] by Cotton-Mouton constant measurements in infinitely dilute solutions succeeded in determining the magnetic polarizabilities  $a_{33}^m$  and  $a_{11}^m$  for a large variety of molecules, all quantities appearing in the right hand term of eq. (9) are now available and we are in a position immediately to calculate the value of the constant  $B_{em}$ . The values thus computed are given in table 1.

Applying a pulse magnetic field of  $10^5$  Oe (as done by Surma [10] when measuring the Cotton-Mouton constant in solutions) for the measurement of electric anisotropy, one sees that for benzene  $\epsilon_{zz} - \epsilon_{xx} = 0.8 \times 10^{-16} H^2 \approx 10^{-6}$  whereas for nitrobenzene  $\epsilon_{zz} - \epsilon_{xx} = 8.6 \times 10^{-14} H^2 \approx 10^{-3}$ . Hence, in nitrobenzene and some other substances (see table 1), existing experimental techniques [10] are adequate for the detection of the electric anisotropy induced by strong magnetic fields.

Doubtless still more considerable effects are to be expected in paramagnetics [6], where even non-linear changes in magnetic permeability [11] have to be envisaged.

It would be highly worth while to carry out dispersion and absorption measurements of the electric anisotropy in the context of eqs. (7). This would provide information regarding the relaxation time  $\tau_2$ , as can be obtained from the Kerr effect [4] and optical birefringence [5,12]. Experimental attempts in this direction are being made in the High Magnetic Fields Laboratory of this Department.
